

MOVING IMAGE DATA CONTROLLING APPARATUS AND METHOD

BACKGROUND OF THE INVENTION

1. Field of the Invention

5 The present invention relates to a moving image data controlling apparatus and a method thereof, particularly, to an apparatus for recording and reproducing a digital moving image and a method thereof. More particularly, the present invention relates to a technique applying a display effect such as displaying
10 in mosaic and making shadings to a specific area in an image when a personal computer or the like displays a digital moving image.

2. Description of the Related Art

As a conventional technique, it is known that, when
15 display of an image is changed such as scrambling in shadings or in mosaic, pixel data is corrected while image source is digitized and is encoded into a digital image.

In the above-described technique, it is necessary
20 to change data for each of pixels constituting the image, therefore, there is a trouble, namely, it needs a complicated procedure. Further, a pixel value is changed once, therefore, it is impossible to make the display effect effective or ineffective according to an

instruction and a password input from an user, and so on.

SUMMARY OF THE INVENTION

It is an object of the present invention to provide
5 a technique applying a display effect such as shadings
and mosaic to a digital moving image, and to provide a
technique capable of dynamically making the display
effect effective or ineffective at real time according
to an input from an user.

10 The present invention introduces the followings in
order to achieve the above-described objects.

That is, the present invention introduces a moving
image data controlling apparatus comprising a moving
image source input unit for inputting moving image data;
15 an information input unit for inputting control
information designating a processing for the moving
image data inputted through said moving image source
input unit; and a data integrating unit for integrating
the moving image data inputted through said moving image
20 source input unit with the control information inputted
through said information input unit.

More concretely, a moving image data controlling
apparatus comprises a digital moving image source input
unit for inputting digital moving image data containing

plural data of a predetermined image unit; an area
information input unit for inputting area information
defined for each predetermined image unit of the digital
moving image data inputted through said moving image
5 source input unit; and a data integrating unit for
integrating the area information inputted through said
area information input unit, as additional information
for all pixels in each predetermined image unit of the
digital moving image data inputted through said digital
10 moving image source input unit, with the digital moving
image data.

The present invention also introduces a moving
image data storing method comprising: a step of
inputting moving image data; a step of inputting control
15 information designating a processing for the inputted
moving image data; a step of integrating the inputted
moving image data with the control information; and a
step of storing the moving image data and the control
information which are integrated.

20 The present invention also introduces a computer
readable medium storing a program making computer
function as a moving image source input unit for
inputting moving image data; an information input unit
for inputting control information designating a

5

10

reproduced.

20

from another event.

The present invention also introduces a moving
image data reproducing method comprising a step of
inputting moving image data; a step of inputting control
5 information designating a processing for the moving
image data; and a step of executing the processing
designated by the control information to a moving image
data stream obtained from the inputted moving image
data.

10 In this case, the data change may be executed while
said moving image data stream is reproduced.

An instruction from an user or another event may be
inputted, and an existence of the data change and/or a
change content may be decided in accordance with the
15 inputted instruction or the inputted event.

The present invention also introduces a computer
readable medium storing a program making computer
function as; a moving image source input unit for
inputting moving image data; an information input unit
20 for inputting control information designating a
processing for the moving image data inputted through
the moving image source input unit; and a data changing
unit for executing data change designated by the control
information to a moving image data stream obtained from

the moving image source input unit.

5 The present invention also introduces a moving
image data controlling apparatus comprising: a digital
moving image source input unit for inputting digital
moving image data containing plural data of a
predetermined image unit; an area information input unit
for inputting area information defined for each
predetermined image unit of the digital moving image
data inputted through said moving image source input
10 unit; and a data changing unit for obtaining a digital
moving image stream from the moving image source input
unit and for executing data change to pixels of the
digital moving image data designated by the control
information in each predetermined image unit of the
15 digital moving image stream.

In this case, the moving image data controlling
apparatus may further comprise an instructing unit for
instructing the data changing unit whether or not a
pixel value is changed and/or how to change the pixel
20 value when the pixel value is changed.

The present invention introduces a moving image
data controlling method comprising: a step of inputting
digital moving image data containing plural data of a
predetermined image unit; a step of inputting area

0024844-00199

information defined for each predetermined image unit of the inputted digital moving image data; a step of obtaining a digital moving image stream from the digital moving image data; and a step of executing data change to pixels of the digital moving image data designated by the control information in each predetermined image unit of the digital moving image stream.

In this method, it may be instructed whether or not a pixel value is changed and/or how to change the pixel value when the pixel value is changed.

The present invention also introduces a computer readable medium storing a program making computer function as; a digital moving image source input unit for inputting digital moving image data containing plural data of a predetermined image unit; an area information input unit for inputting area information defined for each predetermined image unit of the digital moving image data inputted through the moving image source input unit; and a data changing unit for obtaining a digital moving image stream from the moving image source input unit and for executing data change to a pixel of the digital moving image data designated by the control information in each predetermined image unit of the digital moving image stream.

BRIEF DESCRIPTION OF THE DRAWINGS

Other objects and advantages of the present invention will become apparent during the following discussion conjunction with the accompanying drawings, in which:

FIG. 1 is a block diagram showing an encoder according to an embodiment of the present invention;

FIG. 2 is a block diagram showing a decoder according to an embodiment of the present invention;

FIG. 3 is a block diagram showing a decoder according to another embodiment;

FIG. 4 is a view showing a concrete example of an encoder;

FIG. 5 is a view showing a concrete example of a decoder;

FIG. 6 is a view showing another concrete example of a decoder;

FIG. 7 is a view showing an user graphical interface of an instructing unit;

FIG. 8 is a flowchart showing a process according to an embodiment; and

FIG. 9 is a view showing a sample of a bitmap.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENT

<Embodiments>

5 of the present invention.

```

10      moving image stream encoding unit 14 and a multiplexing
      unit 15.

```

15 image source input unit 11 receives digital data
containing frames as predetermined image units.

20 information input unit 12 receives the area information
corresponding to each frame of the digital moving image.

The additional information encoding unit 13 encodes the area information inputted through the area information input unit 12 as additional information for

all pixels in each predetermined image unit of the digital moving image source inputted through the digital moving image source input unit 11.

5 The moving image encoding unit 14 encodes digital moving image stream according to the digital moving image data inputted through the digital moving image source input unit 11.

66720-11300
10 Concretely, a plurality of digital moving image frames formed as time passes are inputted through the digital moving image source input unit 11, and the moving image encoding unit 14 encodes these digital moving image frames into a digital moving format such as MPEG-1 Video.

15 The multiplexing unit 15 synchronizes and multiplexes the additional information with each predetermined fixed image unit of the digital moving image stream based on both outputs from the additional information encoding unit 13 and the moving image encoding unit 14, and outputs them as one piece of data.

20 The area information, for example, is data obtained by sequentially arranging bit maps as time passes, in which 1 bit is allocated to each pixel of the frame and which has an image size equal to the frame size of the digital moving image. The area information is compressed

in a format such as RLE (run-length encode format) and is encoded by the additional information encoding unit 13.

FIG. 2 shows a decoder used in order to display the moving image data encoded by the encoder 10 shown in FIG. 1, the moving image data having additional information for each pixel.

The encoder 20 is provided with a demultiplexing unit 21, an additional information decoding unit 22, a moving image decoding unit 23 and a data changing unit 24.

The demultiplexing unit 21 demultiplexes the multiplexed digital moving image data so as to obtain an encoded additional information and an encoded digital moving image stream data. In other words, the demultiplexing unit 21 separates data encoded by the encoder 10 shown in FIG. 1 into an encoded additional information stream and an encoded digital moving image stream.

The additional information decoding unit 22 decodes the encoded additional information. Concretely, the additional information decoding unit 22 outputs area data for each frame of the digital moving image stream.

The moving image decoding unit 23 decodes the

encoded digital moving image stream data, and outputs each frame of the digital moving image.

5 The data changing unit 24 receives the additional information outputted from the additional information decoding unit 22 and the digital moving image stream outputted from the moving image decoding unit 23, and changes data for a pixel of the digital moving data designated by the area information in each predetermined moving image unit of this digital moving image stream.

10 Concretely, the data changing unit 24 obtains frame data outputted from the digital moving stream decoding unit 23 and area data outputted from the additional information decoding unit 22 corresponding to this frame data, and changes a pixel value of the corresponding

15 area in the frame designated by the additional information.

The frame data outputted from the data changing unit 24 is outputted into a display memory such as VRAM at a constant rate as time passes. In this way, a pixel

20 value of a specified area in an digital moving image is changed, and outputted.

As shown in FIG. 3, an encoder may be provided with an instructing unit 25 instructing the data changing unit 24 at real time whether or not a pixel value is

In other words, the instructing unit 25 detects an user input or an event, and sends a signal instructing the data changing unit 24 how to change data when data is really changed in accordance with the detected user input or event.

In FIG. 1, the digital moving image source input unit 11 receives digital moving image data consisting of predetermined units of data, such as frames and pictures.

20 In other words, area information is defined in
correspondence with the predetermined image unit (such
as frame), and is inputted.

Then, the additional information encoding unit 13 encodes area information inputted through the area

information input unit 12 into additional information for all pixels of each predetermined image unit in the digital moving image source inputted through the digital moving image source input unit 11.

5 The moving image encoding unit 14 encodes the digital moving image stream according to the digital moving image data inputted through the digital moving image source input unit 11.

10 The multiplexing unit 15 multiplexes both outputs from the additional information encoding unit 13 and the moving image encoding unit 14 so as to output one by synchronizing the additional information with each predetermined image unit of the digital moving image stream.

15 With this procedure, encoding of the moving image is finished.

20 When the moving image encoded in the above-described procedure is reproduced, the moving image data having additional information every encoded pixel is displayed.

In FIG. 2, the demultiplexing unit 21 demultiplexes the multiplexed digital moving image data, and obtains the encoded additional information and the encoded digital moving image stream data.

Then, the additional information decoding unit 22 decodes the encoded additional information. The moving image decoding unit 23 decodes the encoded digital moving image stream data.

5 As a result, the data changing unit 24 obtains the area information outputted from the additional information decoding unit 22 and the digital moving image stream outputted from the moving image decoding unit 23, and changes data for a pixel of the digital
10 moving image designated by the area information in each predetermined image unit of this digital moving image stream.

 In this way, the held digital moving image data is not changed, but digital moving image data for display
15 is changed in the display step after decoding.

 As shown in FIG. 3, the instructing unit 25 controls the data changing unit 24. In other words, the instructing unit 25 instructs the data changing unit 24 at real time whether or not the pixel value is changed
20 in accordance with an input from the user or another event and/or how to change the pixel value when the pixel value is changed.

Accordingly, it is possible to determine whether or not the pixel value is changed, and it is possible to easily

memory by a software command, and obtains the digital
moving data 38. Then, the mask data 37 is sent from the
area information input unit 12 to the additional
information encoding unit 13 via the memory as the
5 additional information, and is compressed for each
frame.

The additional information encoding unit 13 in FIG.
1 corresponds to a RLE encoding unit 33 in FIG. 4, which
executes the RLE compression with a software algorithm.
10 The moving image encoding unit 14 in FIG. 1 corresponds
to the MPEG-1 Video encoding unit 34 in FIG. 4, which
executes the MPEG-1 Video encoding by the software
algorithm. The digital image data 38 is sent from the
digital moving image source input unit 11 to the
15 encoding unit 34 via the memory, and is compressed in
the MPEG-1 Video format.

The multiplexing unit 15 receives the RLE-
compressed mask data outputted from the RLE encoding
unit 33 and the data compressed in the MPEG-1 Video
20 format and outputted from the MPEG-1 Video encoding unit
34, and multiplexes both data by a software algorithm.

FIG. 5 shows concrete example of a decoder.

As shown in FIG. 5 a decoder 40 surrounded with a
broken line is carried out with software executed in

0024911-00119

like radiating a reflected light.

Next, an explanation will be given of an decoder of another embodiment with reference to FIG. 6.

As shown in FIG. 6, a digital moving image decoder
5 50 surrounded with a broken line is carried out by a software executed in personal computer.

In FIG. 6, the decoder 50 is similar with the decoder 40 in FIG. 5 expect a data changing unit 44 and an instructing unit 45, therefore, the same numerals are
10 given to other units in the decoder 50 and no explanation is given thereof.

The instructing unit 45 accepts an input from an user's mouse, and instructs the data changing unit 44 how to change the specified pixel value with the
15 additional information in the frame data of the moving image.

More detailed explanations will be given with reference to FIG. 7.

FIG. 7 shows a graphical user interface of the
20 instructing unit 45 in FIG. 6, which is a dialog box displayed on a screen.

As shown in FIG. 7, the instructing unit 45 consists of graphical buttons 61, 62, 63. These buttons 61, 62, 63 can be selected by clicking the mouse or the

like. The instructing unit 45 keeps a variable "n" inside, and the variable becomes "n=1" when the button "no mosaic" 61 is clicked, the variable becomes "n=4" when the button "4 dots mosaic" 62 is clicked, and the variable becomes "n=8" when the button "8 dots mosaic" 62 is clicked.

This variable "n" is sent to the data changing unit 44 shown in FIG. 6.

Next, explanations will be given of an action of the data changing unit 24 shown in FIGs. 5 and 6 with reference to a flowchart shown FIG. 8.

This flowchart shows an algorithm applying an image effect "4x4 dot mosaic" to a pixel of the digital moving image corresponding to the dot of the mask data when the value of the mask data is 1.

In FIG. 8, one pixel of the digital moving image data to be displayed is obtained in the step 101. Subsequently, in the step 102, the mask data corresponding to the pixel obtained in the step 101 is obtained. Then, in step 103, a value of the mask data obtained in the step 102 is checked, and the pixel value of the digital image data to be displayed is changed when the value of the mask data is 1. In the step 103, when the value of the mask data is not 1, the process is

advanced to the step 107 and digital image data is
outputted without changing the pixel value of the
digital image data. In the steps 104, 105 and 106, the
pixel value is processed, namely, when the image is
5 divided into 4×4 dot tiles, the pixel value is changed
for a pixel value at an upper left pixel in the same
tile. In other words, in step 104, the row address of
the current pixel is divided by n, an integer is picked
up, and a value X is obtained by multiplying this
10 integer by n. Subsequently, in the step 105, the column
address of the current pixel is divided by n, an integer
is picked up, and a value Y is obtained by multiplying
this integer by n. Finally, the current pixel value is
changed for the pixel value of the row address X and the
15 column address Y, and the changed pixel value is
outputted. In this way, the image effect "mosaic" can be
applied only to the image at the area designated by mask
data.

It is also possible to display another image effect
20 such as shadings by changing the process in the steps
104, 105 and 106 into another process with the buttons
61, 62 and 63 shown in FIG. 7.

As to an algorithm carrying out "shadings", for
example, it is possible to use a method in which an

An example will be explained of a method of

10 obtained by decreasing the visibility.

15 and each pixel value after applying "shadings" process
is shown by PI'00, PI'10, ... PI'22.

with the following formula;

```

20      PI'11= (PI00+PI10+PI20+PI01+3×PI11+PI21+PI02+PI12+
      PI22)/11.

```

This calculation is carried out for original brightness information of all pixels, and the original brightness information is changed for the obtained

brightness information, thereby obtaining "shadings" effect.

Incidentally, there is a case in that some of pixels for this calculation can not be obtained at the image data periphery. In this case, a term corresponding to lack pixel datum is excluded, and new brightness information is calculated by using a formula in which the value 11 of denominator is changed for a value obtained by subtracting a number of lacking pixels from the value 11.

For example, when pixels P00, P10, P20 can not obtained, the formula is changed as follows;

$$PI'11 = (PI01 + 3 \times PI11 + PI21 + PI02 + PI12 + PI22) / 8.$$

When P00, P10, P20, P01, P02 can not obtained, the formula is changed as follows;

$$PI'11 = (3 \times PI11 + PI21 + PI12 + PI22) / 6.$$

FIG. 7 shows a flowchart of the action of the data changing unit 24 and 44 in FIGs. 5 and 6 respectively, and the algorithm of this flowchart shows that, when the value of the mask data is "1", the "mosaic" image effect of n×n dot roughness is applied to pixels in the digital moving image corresponding to dots of this mask data. In this way, a user can watch (display) a specific area of the reproduced digital moving image in an original form,

in detailed mosaic or in rough mosaic. Then, in FIG. 6, the instructing unit 45 can switch an existence of change such as "mosaic" at real time.

As above described, in this embodiment, as to a specific area in a digital moving image, pixel data of the digital moving image outputted for display is changed without directly changing pixel data of an original digital moving image, therefore, it is possible to add display effects such as shadings or mosaic easily. An user can also dynamically switch execution/non-execution of the above-described display effects at real time. In other words, it is possible to change a display situation and a screen effect in accordance with an instruction of a user, and it is possible to apply these embodiments to any case, i.e. it is possible to usually display an image harmful to a young person uncleanly and to display the image clearly when a password is inputted.

This invention being thus described, it will be obvious that same may be varied in various ways. Such variations are not to be regarded as departure from the spirit and scope of the invention, and all such modifications would be obvious for one skilled in the art intended to be included within the scope of the

following claims.

[illegible]
